Mechanism of action

Receptor binding profile

Olanzapine is an antipsychotic, antimanic and mood-stabilising agent with affinity for several receptor families. It has greater affinity for serotonin 5-HT2 than dopamine D2 receptors.[1]

Across the dose range of 5–20 mg/day, 5-HT2 occupancy was above 90%, while D2 occupancy rose with dose to a mean of 76% at 20 mg/day.[1,2]

Recept

D1–5	5-HT	H1	M1–5	α1
Dopamine	Serotonin 2A/2C, 3, 6	Histamine	Muscarinic	Adrenergic

Receptor families at which olanzapine showed affinity (Ki < 100 nM) in preclinical studies. Order does not indicate relative affinity.[1]

Manic episode, monotherapy
Manic episode, combination therapy
Prevention of recurrence in bipolar disorder

Important safety information

Contraindications

Hypersensitivity to olanzapine or any excipient; known risk of narrow-angle glaucoma.[1]

Dementia-related psychosis

Not recommended: increased mortality and risk of cerebrovascular accident in elderly patients.[1]

Weight and metabolic changes

Monitor weight, blood glucose and lipids at baseline and regularly during treatment.[1]

Neuroleptic malignant syndrome

If signs occur, all antipsychotic medicines, including olanzapine, must be discontinued.[1]
